

Fukushima type decomposition for semi-Dirichlet forms^{*}

Zhi-Ming Ma, Wei Sun and Li-Fei Wang

Abstract. We present a Fukushima type decomposition in the setting of general quasi-regular semi-Dirichlet forms. The decomposition is then employed to give a transformation formula for martingale additive functionals. Applications of the results to some concrete examples of semi-Dirichlet forms are given at the end of the paper. We discuss also the uniqueness question about Doob-Meyer decomposition on optional sets of interval type.

Key words and phrases. Fukushima type decomposition, quasi-regular semi-Dirichlet forms, stochastic sets of interval type, transformation formula for martingale additive functionals.

2000 Mathematics Subject Classification. Primary 31C25; Secondary 60J25.

1 Introduction

The celebrated Fukushima's decomposition and related transformation rules play the roles of Doob-Meyer decomposition and Itô's formula in the framework of Dirichlet forms. They have been used to investigate the properties of a large class of stochastic processes that are not semi-martingales such as additive functionals of Brownian motion which are not necessarily of bounded variation (cf. e.g. [23], [3] and references therein). Fukushima's decomposition was originally established for regular symmetric Dirichlet forms (cf. [5] and [6, Theorem 5.2.2]) and then extended to the non-symmetric and quasi-regular cases (cf. [18, Theorem 5.1.3] and [16, Theorem VI.2.5]). Suppose that $(\mathcal{E}, D(\mathcal{E}))$ is a quasi-regular Dirichlet form on $L^2(E; m)$ with associated Markov process $((X_t)_{t \geq 0}, (P_x)_{x \in E_\Delta})$ (we refer the reader to [6, 16, 15] for notations and terminologies of this paper). If $u \in D(\mathcal{E})$, then Fukushima's decomposition tells us that there exist a unique martingale additive functional (MAF in short) $M^{[u]}$ of finite energy and a continuous additive functional $N^{[u]}$ of zero energy such that

$$\tilde{u}(X_t) - \tilde{u}(X_0) = M_t^{[u]} + N_t^{[u]}. \quad (1.1)$$

^{*}We are grateful to the support of 973 project (2011CB808000), NCMIS, NSFC (11021161), and NSERC (Grant No. 311945-2013).

Hereafter \tilde{u} denotes an \mathcal{E} -quasi-continuous m -version of u .

Compared with Dirichlet form, semi-Dirichlet form is a more general framework arising from various applications. In the viewpoint of applications, and also by the interests of the theory its own, it is natural to ask if we can extend Fukushima's decomposition from the setting of Dirichlet forms to that of semi-Dirichlet forms. For example, do we have Fukushima's decomposition for the following simple local semi-Dirichlet form?

$$\mathcal{E}(u, v) = \int_0^1 u'v'dx + \int_0^1 \sqrt{x}u'vdx, \quad u, v \in D(\mathcal{E}) := H_0^{1,2}(0, 1).$$

Note that the assumption of the existence of dual Markov process plays a crucial role in Fukushima's decomposition for Dirichlet forms. In fact, without that assumption, the usual definition of energy of AFs is questionable. Here we would like to point out that although Fukushima's decomposition was even considered for generalized Dirichlet forms (cf. [24] and [22]), which is a more general framework than semi-Dirichlet forms (see [21]), up to now Fukushima's decomposition for generalized Dirichlet forms has only been given under the additional assumption that their dual forms are also sub-Markovian. For a quasi-regular semi-Dirichlet form $(\mathcal{E}, D(\mathcal{E}))$, we may use the semi- h transform method to associate $(\mathcal{E}, D(\mathcal{E}))$ with a sub-Markovian dual form (cf. [8]). However, without imposing further assumptions, we cannot expect to obtain Fukushima's decomposition for general $u \in D(\mathcal{E})$; we can only expect to obtain the decomposition (1.1) for functions u in the domain of the generator of $(\mathcal{E}, D(\mathcal{E}))$, which is just the classical Doob-Meyer decomposition.

To our knowledge, the paper [14] appears to be the first publication on the Fukushima type decomposition in the semi-Dirichlet forms setting without assuming that the dual form is sub-Markovian. In that paper the authors introduced a condition of local control (cf. Condition 2.5 below) and under the condition they obtained the Fukushima type decomposition for $u \in D(\mathcal{E})_{loc}$ where $(\mathcal{E}, D(\mathcal{E}))$ is a local semi-Dirichlet form. The main method employed in [14] is the localization and pasting technique. For a non-local semi-Dirichlet form, the jump part of $M^{[u]}$ is in general not locally consistent, which causes some extra difficulty in implementing the localization and pasting technique. Afterwards, one of the authors of the present paper investigated further in [26] on the Fukushima type decomposition for general quasi-regular semi-Dirichlet forms. Motivated by some idea of Kuwae [13] and employing also the localization and pasting technique, he obtained the Fukushima type decomposition for $u \in D(\mathcal{E})_{loc}$ under a suitable condition (S) (see Theorem 2.4 below). Meanwhile Professor Oshima sent us a manuscript of his new book [19], in which he proved Fukushima's decomposition for $u \in D(\mathcal{E})_b$ in the setting of regular semi-Dirichlet forms satisfying his condition $(\mathcal{E}.5)$. The main techniques employed by Oshima in developing Fukushima's decomposition are the weak sense energy and his genius auxiliary bilinear form, different from the localization and pasting technique employed in [14] and [26].

In this paper we shall report and develop further the Fukushima type decomposition based on [26], and discuss some related topics. Let $(\mathcal{E}, D(\mathcal{E}))$ be a quasi-regular semi-Dirichlet form which is not necessarily local. We show that under a suitable assumption (i.e. Assumption 2.3 below), a function $u \in D(\mathcal{E})_{loc}$ admits a Fukushima type decomposition if and only if it satisfies Condition (S), and the decomposition is unique. Roughly speaking, here u admits a Fukushima type decomposition means that

$$\tilde{u}(X_t) - \tilde{u}(X_0) = M_t^{[u]} + N_t^{[u]},$$

where $M^{[u]}$ is a locally square integrable MAF on the set $I(\zeta) := \llbracket 0, \zeta \cup \llbracket \zeta_i \rrbracket$, with ζ being the lifetime of X and ζ_i the totally inaccessible part of ζ ; and $N^{[u]}$ is a local AF which is continuous and has zero quadratic variation on $I(\zeta)$. For details see Theorem 2.4 below. It is worth to point out that Assumption 2.3 mentioned above is weaker than the condition of local control in [14] and the condition $(\mathcal{E}.5)$ in [19]. We are very grateful to Professor Oshima for sending us his new book [19]. The condition $(\mathcal{E}.5)$ in [19] stimulated us to formulate Assumption 2.3.

The reader might notice that in the above description we used $I(\zeta)$ instead of $\llbracket 0, \zeta \rrbracket$, the latter is customarily used in the literature. The reason of this variation is that we discovered that the decomposition on $I(\zeta)$ is unique, but it may fail to be unique on $\llbracket 0, \zeta \rrbracket$. This difference is essentially due to the fact that $I(\zeta)$ is a predictable set of interval type while $\llbracket 0, \zeta \rrbracket$ is not necessarily predictable. This discovery exposes not only an oversight in the previous paper [14], but also similar oversights in the literature e.g. [2] and [13]. The oversight may be traced back even to Theorem 8.26 of the book [9], which exposes a question about the uniqueness of Doob-Meyer decomposition on optional sets of interval type. We shall discuss this question in detail in Section 3 below.

The rest of the paper is organized as follows. In Section 2, we present a general Fukushima type decomposition for semi-Dirichlet forms. We divide it into two subsections. In Subsection 2.1 we present basic settings and statement of the theorem, and provide some discussions and remarks about the theorem. In Subsection 2.2, we give the proof of the theorem. In Section 3, we discuss in detail the question about the uniqueness of Doob-Meyer decomposition on optional sets of interval type. In Section 4, we give a transformation formula for MAFs based on the Fukushima type decomposition. In Section 5, we apply our results to two concrete examples of semi-Dirichlet forms appearing in recent papers.

2 Fukushima type decomposition

2.1 Statement of the theorem and discussions

The basic setting of this paper is the same as that in [14] with some necessary modifications, e.g., $(\mathcal{E}, D(\mathcal{E}))$ in this paper is not assumed to be local. To fix the

notations and also for the convenience of the reader, below we restate our setting of which some contents are taken from [14]. Let E be a metrizable Lusin space and m a σ -finite positive measure on its Borel σ -algebra $\mathcal{B}(E)$. We consider a quasi-regular semi-Dirichlet form $(\mathcal{E}, D(\mathcal{E}))$ on $L^2(E; m)$. Hereafter for notations and terminologies related to quasi-regular semi-Dirichlet forms we refer to [15]. Denote by $(T_t)_{t \geq 0}$ and $(G_\alpha)_{\alpha \geq 0}$ (resp. $(\hat{T}_t)_{t \geq 0}$ and $(\hat{G}_\alpha)_{\alpha \geq 0}$) the semigroup and resolvent (resp. co-semigroup and co-resolvent) associated with $(\mathcal{E}, D(\mathcal{E}))$. Let $\mathbf{M} = (\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, (X_t)_{t \geq 0}, (P_x)_{x \in E_\Delta})$ be an m -tight special standard process which is properly associated with $(\mathcal{E}, D(\mathcal{E}))$ in the sense that $P_t f$ is an \mathcal{E} -quasi-continuous m -version of $T_t f$ for all $f \in \mathcal{B}_b(E) \cap L^2(E; m)$ and all $t > 0$, where $(P_t)_{t \geq 0}$ denotes the semigroup associated with \mathbf{M} (cf. [15, Theorem 3.8]).

Similar to the symmetric case, in the semi-Dirichlet forms setting there is also a one-to-one correspondence between the family of all equivalent classes of positive continuous additive functionals and the family S of smooth measures. The contents below concerning positive continuous additive functionals and S are taken from [14]. We remark that the reader can now find more detailed descriptions and discussions in [19] on the potential theory of semi-Dirichlet forms including the correspondence between positive continuous additive functionals and smooth measures.

Recall that a positive measure μ on $(E, \mathcal{B}(E))$ is called *smooth* (w.r.t. $(\mathcal{E}, D(\mathcal{E}))$), denoted by $\mu \in S$, if $\mu(N) = 0$ for each \mathcal{E} -exceptional set $N \in \mathcal{B}(E)$ and there exists an \mathcal{E} -nest $\{F_k\}$ of compact subsets of E such that

$$\mu(F_k) < \infty \text{ for all } k \in \mathbb{N}.$$

A family $(A_t)_{t \geq 0}$ of functions on Ω is called an *additive functional* (AF in short) of \mathbf{M} if:

- (i) A_t is \mathcal{F}_t -measurable for all $t \geq 0$.
- (ii) There exists a defining set $\Lambda \in \mathcal{F}$ and an exceptional set $N \subset E$ which is \mathcal{E} -exceptional such that $P_x[\Lambda] = 1$ for all $x \in E \setminus N$, $\theta_t(\Lambda) \subset \Lambda$ for all $t > 0$ and for each $\omega \in \Lambda$, $t \rightarrow A_t(\omega)$ is right continuous on $(0, \infty)$ and has left limits on $(0, \zeta(\omega))$, $A_0(\omega) = 0$, $|A_t(\omega)| < \infty$ for $t < \zeta(\omega)$, $A_t(\omega) = A_{\zeta}(\omega)$ for $t \geq \zeta(\omega)$, and

$$A_{t+s}(\omega) = A_t(\omega) + A_s(\theta_t \omega), \quad \forall s, t \geq 0. \quad (2.1)$$

Hereafter ζ denotes the lifetime of $X := (X_t)_{t \geq 0}$.

Two AFs $A = (A_t)_{t \geq 0}$ and $B = (B_t)_{t \geq 0}$ are said to be equivalent, denoted by $A = B$, if they have a common defining set Λ and a common exceptional set N such that $A_t(\omega) = B_t(\omega)$ for all $\omega \in \Lambda$ and $t \geq 0$. An AF $A = (A_t)_{t \geq 0}$ is called a continuous AF (CAF in short) if $t \rightarrow A_t(\omega)$ is continuous on $(0, \infty)$. It is called a positive CAF (PCAF in short) if $A_t(\omega) \geq 0$ for all $t \geq 0$, $\omega \in \Lambda$.

Lemma 2.1. (cf. [14, Theorem A.8], see also [19, Section 4.1]) *Let A be a PCAF. Then there exists a unique $\mu \in S$, which is referred to as the Revuz measure of A and is denoted by μ_A , such that:*

For any γ -co-excessive function g ($\gamma \geq 0$) in $D(\mathcal{E})$ and $f \in \mathcal{B}^+(E)$,

$$\lim_{t \downarrow 0} \frac{1}{t} E_{g \cdot m}((fA)_t) = \langle f \cdot \mu, \tilde{g} \rangle.$$

Conversely, let $\mu \in S$, then there exists a unique (up to the equivalence) PCAF A such that $\mu = \mu_A$.

Throughout this paper, we fix a function $\phi \in L^2(E; m)$ with $0 < \phi \leq 1$ m -a.e. and set $h = G_1\phi$, $\hat{h} = \hat{G}_1\phi$. Denote $\tau_B := \inf\{t > 0 \mid X_t \notin B\}$ for $B \subset E$. Let V be a quasi-open subset of E . We denote by $X^V = (X_t^V)_{t \geq 0}$ the part process of X on V and denote by $(\mathcal{E}^V, D(\mathcal{E})_V)$ the part form of $(\mathcal{E}, D(\mathcal{E}))$ on $L^2(V; m)$. It is known that X^V is a standard process and $(\mathcal{E}^V, D(\mathcal{E})_V)$ is a quasi-regular semi-Dirichlet form (cf. [12]). Denote by $(T_t^V)_{t \geq 0}$, $(\hat{T}_t^V)_{t \geq 0}$, $(G_\alpha^V)_{\alpha \geq 0}$ and $(\hat{G}_\alpha^V)_{\alpha \geq 0}$ the semigroup, co-semigroup, resolvent and co-resolvent associated with $(\mathcal{E}^V, D(\mathcal{E})_V)$, respectively. One can check that $\hat{h}|_V$ is 1-co-excessive w.r.t. $(\mathcal{E}^V, D(\mathcal{E})_V)$. Define $\bar{h}^V := \hat{h}|_V \wedge \hat{G}_1^V \phi$. Then $\bar{h}^V \in D(\mathcal{E})_V$ and \bar{h}^V is 1-co-excessive. Denote $D(\mathcal{E})_{V,b} := \mathcal{B}_b(E) \cap D(\mathcal{E})_V$.

For an AF $A = (A_t)_{t \geq 0}$ of X^V , we define

$$e^V(A) := \lim_{t \downarrow 0} \frac{1}{2t} E_{\bar{h}^V \cdot m}(A_t^2)$$

whenever the limit exists in $[0, \infty]$. Define

$$\begin{aligned} \dot{\mathcal{M}}^V &:= \{M \mid M \text{ is an AF of } X^V, E_x(M_t^2) < \infty, E_x(M_t) = 0 \\ &\quad \text{for all } t \geq 0 \text{ and } \mathcal{E}\text{-q.e. } x \in V, e^V(M) < \infty\}, \end{aligned}$$

$$\begin{aligned} \mathcal{N}_c^V &:= \{N \mid N \text{ is a CAF of } X^V, E_x(|N_t|) < \infty \text{ for all } t \geq 0 \\ &\quad \text{and } \mathcal{E}\text{-q.e. } x \in V, e^V(N) = 0\}, \end{aligned}$$

$$\begin{aligned} \Theta &:= \{\{V_n\} \mid V_n \text{ is } \mathcal{E}\text{-quasi-open, } V_n \subset V_{n+1} \text{ } \mathcal{E}\text{-q.e.} \\ &\quad \forall n \in \mathbb{N}, \text{ and } E = \bigcup_{n=1}^\infty V_n \text{ } \mathcal{E}\text{-q.e.}\}, \end{aligned}$$

and

$$\begin{aligned} D(\mathcal{E})_{loc} &:= \{u \mid \exists \{V_n\} \in \Theta \text{ and } \{u_n\} \subset D(\mathcal{E}) \\ &\quad \text{such that } u = u_n \text{ } m\text{-a.e. on } V_n, \forall n \in \mathbb{N}\}. \end{aligned}$$

In what follows we shall employ the notion of local AFs introduced in [6] as follows.

Definition 2.2. (cf. [6, page 271]) A family $A = (A_t)_{t \geq 0}$ of functions on Ω is called a local AF of \mathbf{M} , if A satisfies all the requirements for an AF as stated in above (i) and (ii), except that the additivity property (2.1) is required only for $s, t \geq 0$ with $t + s < \zeta(\omega)$.

Two local AFs $A^{(1)}, A^{(2)}$ are said to be equivalent if for \mathcal{E} -q.e. $x \in E$, it holds that

$$P_x(A_t^{(1)} = A_t^{(2)}; t < \zeta) = P_x(t < \zeta), \quad \forall t \geq 0.$$

We now define

$$\begin{aligned} \dot{\mathcal{M}}_{loc} := \{ & M \mid M \text{ is a local AF of } \mathbf{M}, \exists \{V_n\}, \{E_n\} \in \Theta \text{ and } \{M^n \mid M^n \in \dot{\mathcal{M}}^{V_n}\} \\ & \text{such that } E_n \subset V_n, M_{t \wedge \tau_{E_n}} = M_{t \wedge \tau_{E_n}}^n, t \geq 0, n \in \mathbb{N} \} \end{aligned}$$

and

$$\begin{aligned} \mathcal{L}_c := \{ & N \mid N \text{ is a local AF of } \mathbf{M}, \exists \{E_n\} \in \Theta \text{ such that } t \rightarrow N_{t \wedge \tau_{E_n}} \\ & \text{is continuous and of zero quadratic variation, } n \in \mathbb{N} \}. \end{aligned}$$

We use ζ_i to denote the totally inaccessible part of ζ , by which we mean that ζ_i is an $\{\mathcal{F}_t\}$ -stopping time and is the totally inaccessible part of ζ w.r.t. P_x for \mathcal{E} -q.e. $x \in E$. In Section 3 below we shall give a proof for the existence and uniqueness of such ζ_i , where the uniqueness is in the sense of P_x -a.s. for \mathcal{E} -q.e. $x \in E$. Write $I(\zeta) := \llbracket 0, \zeta \llbracket \cup \llbracket \zeta_i \rrbracket$. We can show that there exists a $\{V_n\} \in \Theta$ such that for any $\{U_n\} \in \Theta$, $I(\zeta) = \cup_n \llbracket 0, \tau_{V_n \cap U_n} \rrbracket$ P_x -a.s. for \mathcal{E} -q.e. $x \in E$ (see Proposition 3.4 below). Therefore $I(\zeta)$ is a predictable set of interval type (cf. [9, Theorem 8.18]). In this paper a local AF M is called a locally square integrable MAF on $I(\zeta)$, denoted by $M \in \mathcal{M}_{loc}^{I(\zeta)}$, if $M \in (\mathcal{M}_{loc}^2)^{I(\zeta)}$ in the sense of [9, Definition 8.19].

Denote by $J(dx, dy)$ the jump measure of $(\mathcal{E}, D(\mathcal{E}))$ (cf. [10]). Let $(N(x, dy), H_s)$ be a Lévy system of X . Then we have $J(dy, dx) = N(x, dy)\mu_H(dx)$.

We put the following assumption:

Assumption 2.3. *There exist $\{V_n\} \in \Theta$ and locally bounded function $\{C_n\}$ on \mathbb{R} such that for each $n \in \mathbb{N}$, if $u, v \in D(\mathcal{E})_{V_n, b}$ then $uv \in D(\mathcal{E})$ and*

$$\mathcal{E}(uv, uv) \leq C_n(\|u\|_\infty + \|v\|_\infty)(\mathcal{E}_1(u, u) + \mathcal{E}_1(v, v)).$$

Now we can state the main theorem of this section.

Theorem 2.4. *Suppose that $(\mathcal{E}, D(\mathcal{E}))$ is a quasi-regular semi-Dirichlet form on $L^2(E; m)$ satisfying Assumption 2.3. Then for $u \in D(\mathcal{E})_{loc}$ the following two assertions are equivalent to each other.*

(i) *u admits a Fukushima type decomposition. That is, there exist $M^{[u]} \in \mathcal{M}_{loc}^{I(\zeta)}$ and $N^{[u]} \in \mathcal{L}_c$ such that*

$$\tilde{u}(X_t) - \tilde{u}(X_0) = M_t^{[u]} + N_t^{[u]}, \quad t \geq 0, \quad P_x\text{-a.s. for } \mathcal{E}\text{-q.e. } x \in E. \quad (2.2)$$

(ii) *u satisfies Condition (S) specified below.*

$$(S) : \quad \mu_u(dx) := \int_E (\tilde{u}(x) - \tilde{u}(y))^2 J(dy, dx) \text{ is a smooth measure.}$$

Moreover, if u satisfies Condition (S), then the decomposition (2.2) is unique up to the equivalence of local AFs, and the continuous part of $M^{[u]}$ belongs to \mathcal{M}_{loc} .

The proof of Theorem 2.4 will be given in the next subsection. In the remainder of this subsection we provide some remarks and discussions about the theorem.

In [14], the authors obtained a Fukushima type decomposition for $u \in D(\mathcal{E})_{loc}$ where $(\mathcal{E}, D(\mathcal{E}))$ is a local quasi-regular Dirichlet form satisfying the condition of local control as stated below.

Condition 2.5. *There exists $\{V_n\} \in \Theta$ such that for each $n \in \mathbb{N}$ there exist a Dirichlet form $(\eta^{(n)}, D(\eta^{(n)}))$ on $L^2(V_n; m)$ and a constant $C_n > 1$ satisfying $D(\eta^{(n)}) = D(\mathcal{E})_{V_n}$ and for any $u \in D(\mathcal{E})_{V_n}$,*

$$\frac{1}{C_n} \eta_1^{(n)}(u, u) \leq \mathcal{E}_1(u, u) \leq C_n \eta_1^{(n)}(u, u).$$

It is clear that Assumption 2.3 is more general than Condition 2.5. Hence we have the following remark.

Remark 2.6. *Theorem 2.4 extends the corresponding result of [14].*

In [19], Oshima discussed various topics of regular semi-Dirichlet forms under his condition (E.5). In particular, he proved in Theorem 5.1.5 a weak sense of Fukushima's decomposition for $u \in D(\mathcal{E})_b$. Below is the condition (E.5) of [19] stated in our context.

Condition (E.5). If $u, v \in D(\mathcal{E})$ and $w \in L^2(E; m)$ satisfy $|w(x) - w(y)| \leq |u(x) - u(y)| + |v(x) - v(y)|$ and $|w(x)| \leq |u(x)| + |v(x)|$ for any $x, y \in E$, then $w \in D(\mathcal{E})$ and $|\mathcal{E}(w, w)| \leq K(\mathcal{E}_1(u, u) + \mathcal{E}_1(v, v))$ for some K depending on $\|u\|_\infty$ and $\|v\|_\infty$.

It is easy to see that Condition (E.5) implies the following condition.

Condition 2.7. *There exists a locally bounded function C on \mathbb{R} such that if $u, v \in D(\mathcal{E})_b$, then $uv \in D(\mathcal{E})$ and*

$$\mathcal{E}(uv, uv) \leq C(\|u\|_\infty + \|v\|_\infty)(\mathcal{E}_1(u, u) + \mathcal{E}_1(v, v)). \quad (2.3)$$

Proposition 2.8. *Suppose that $(\mathcal{E}, D(\mathcal{E}))$ satisfies Condition 2.7, then any $u \in D(\mathcal{E})_b$ satisfies Condition (S), and hence admits a Fukushima type decomposition.*

Proof. Since Condition 2.7 is a special case of Assumption 2.3, hence by Theorem 2.4 we need only to check that any $u \in D(\mathcal{E})_b$ satisfies Condition (S). By the quasi-homeomorphism method (cf. [4] or [10, Theorem 3.8]), without loss of generality below we assume that $(\mathcal{E}, D(\mathcal{E}))$ is a regular semi-Dirichlet form. Let $\{E_n\}$ be a sequence of relatively compact open sets such that $E = \cup_n E_n$ and $\{u_n\} \subset$

$D(\mathcal{E}) \cap C_0(E)$ satisfying $u_n = 1$ on E_n for each $n \in \mathbb{N}$. We choose a sequence of relatively compact open sets $G_l \uparrow E$ and a sequence of numbers $\delta_l \downarrow 0$ such that the set $\Gamma_l := \{(x, y) \in G_l \times G_l \mid \rho(x, y) \geq \delta_l\}$ is a continuous set w.r.t. J for every $l \in \mathbb{N}$, where ρ is the metric of E . For $\beta > 0$, let σ_β be the unique positive Radon measures on $E \times E$ satisfying

$$(\beta G_\beta f, g) = \int_{E \times E} f(x)g(y)\sigma_\beta(dxdy), \quad \forall f, g \in D(\mathcal{E}) \cap C_0(E).$$

Let $u \in D(\mathcal{E}) \cap C_0(E)$. Then, for each $n \in \mathbb{N}$,

$$\begin{aligned} & \int_{E_n} \int_E (u(x) - u(y))^2 N(x, dy) \mu_H(dx) \\ & \leq \int_E \int_E u_n(x) (u(x) - u(y))^2 N(x, dy) \mu_H(dx) \\ & \leq \lim_{l \rightarrow \infty} \int_{\Gamma_l} \int_{\Gamma_l} (u(x) - u(y))^2 u_n(y) J(dx, dy) \\ & = \lim_{l \rightarrow \infty} \lim_{\beta \rightarrow \infty} \frac{\beta}{2} \int_{\Gamma_l} \int_{\Gamma_l} (u(x) - u(y))^2 u_n(y) \sigma_\beta(dx, dy) \\ & \leq \lim_{\beta \rightarrow \infty} \frac{\beta}{2} \int_E \int_E (u(x) - u(y))^2 u_n(y) \sigma_\beta(dx, dy) \\ & \leq \lim_{\beta \rightarrow \infty} \frac{\beta}{2} \{(\beta G_\beta 1_E, u^2 u_n) - 2(\beta G_\beta u, u u_n) + (\beta G_\beta u^2, u_n)\} \\ & \leq \lim_{\beta \rightarrow \infty} \{\beta(u - \beta G_\beta u, u u_n) - \frac{\beta}{2}(u^2 - \beta G_\beta u^2, u_n)\} \\ & = \mathcal{E}(u, u u_n) - \frac{1}{2} \mathcal{E}(u^2, u_n), \end{aligned} \tag{2.4}$$

which implies that u satisfies Condition (S).

For general $u \in D(\mathcal{E})_b$, we may select a sequence of functions $\{u_k\} \subset D(\mathcal{E}) \cap C_0(E)$ such that $u_k \rightarrow u$ w.r.t. the $\tilde{\mathcal{E}}_1^{1/2}$ -norm as $k \rightarrow \infty$ and $\|u_k\|_\infty \leq \|u\|_\infty$ for $k \in \mathbb{N}$. Then by (2.3), (2.4) and Fatou's lemma, we can show that $\int_{E_n} \int_E (\tilde{u}(x) - \tilde{u}(y))^2 N(x, dy) \mu_H(dx) < \infty$. Hence u satisfies Condition (S), which completes the proof. \square

Remark 2.9. *Proposition 2.8 shows that Theorem 2.4 is an extension of [19, Theorem 5.1.5].*

We would like to point out that the methods of [19] in developing Fukushima's decomposition are different from ours. In the next subsection we shall see that Theorem 2.4 is proved by the localization and pasting technique. The main techniques employed by Oshima in developing his Theorem 5.1.5 are the weak sense energy and the genius auxiliary bilinear form invented in [19]. We take this opportunity to thank Professor Oshima for sending us his manuscript [19]. The condition $(\mathcal{E}.5)$ in [19] stimulated us to formulate Assumption 2.3.

Remark 2.10. *Theorem 2.4 extends the corresponding results of [6, Theorem 5.5.1] and [13, Theorem 4.2] from the symmetric case to the semi-Dirichlet form case.*

Note that for a symmetric Dirichlet form $(\mathcal{E}, D(\mathcal{E}))$, Assumption 2.3 is satisfied automatically. Also, $u \in D(\mathcal{E})_{loc}$ satisfies Condition (S) trivially if $(\mathcal{E}, D(\mathcal{E}))$ is local. When $(\mathcal{E}, D(\mathcal{E}))$ is non-local, Condition (S) is necessary even in the symmetric case. In developing stochastic analysis with Nakao's integral, Kuwae obtained in [13] a generalized Fukushima decomposition in the symmetric case for a subclass of $D(\mathcal{E})_{loc}$, which is equivalent to impose Condition (S) for $u \in D(\mathcal{E})_{loc}$. In this paper when dealing with purely discontinuous part of $M^{[u]}$, we adopted some idea from [13] without making use of Nakao's integral. One of the authors of this paper has joint work with others extending Nakao's integral to non-symmetric Dirichlet forms (cf. [1]). We feel that Nakao's integral can also be extended to semi-Dirichlet forms.

Remark 2.11. *In Theorem 2.4 if we use $\mathcal{M}_{loc}^{[0, \zeta]}$ instead of $\mathcal{M}_{loc}^{I(\zeta)}$, then the uniqueness of the decomposition may fail to be true.*

We shall discuss the above remark and related topics in detail in Section 3 below.

2.2 Proof of the theorem

Before proving Theorem 2.4, we prepare some lemmas.

We fix a $\{V_n\} \in \Theta$ satisfying Assumption 2.3. Without loss of generality, we assume that \hat{h} is bounded on each V_n , otherwise we may replace V_n by $V_n \cap \{\hat{h} < n\}$. To simplify notations, we write

$$\bar{h}_n := \bar{h}^{V_n}.$$

Lemma 2.12. *([14, Lemma 2.6]) Let $u \in D(\mathcal{E})_{V_n, b}$. Then there exist unique $M^{n, [u]} \in \dot{\mathcal{M}}^{V_n}$ and $N^{n, [u]} \in \mathcal{N}_c^{V_n}$ such that for \mathcal{E} -q.e. $x \in V_n$,*

$$\tilde{u}(X_t^{V_n}) - \tilde{u}(X_0^{V_n}) = M_t^{n, [u]} + N_t^{n, [u]}, \quad t \geq 0, \quad P_x\text{-a.s.}$$

Lemma 2.12 has been given in [14] under Assumption 2.5 and the additional assumption that $(\mathcal{E}, D(\mathcal{E}))$ is local; however, it can be easily extended to general semi-Dirichlet forms under Assumption 2.3 with the similar proof.

We now fix a $u \in D(\mathcal{E})_{loc}$ satisfying Condition (S). Then there exist $\{V_n^1\} \in \Theta$ and $\{u_n\} \subset D(\mathcal{E})$ such that $u = u_n$ m -a.e. on V_n^1 . By [15, Proposition 3.6], we may assume without loss of generality that each u_n is \mathcal{E} -quasi-continuous. By [15, Proposition 2.16], there exists an \mathcal{E} -nest $\{F_n^2\}$ of compact subsets of E such that $\{u_n\} \subset C\{F_n^2\}$. Denote by V_n^2 the finely interior of F_n^2 . Then $\{V_n^2\} \in \Theta$. Since u satisfies Condition (S), there exists an \mathcal{E} -nest $\{F_n^3\}$ of compact subsets of E

such that $\mu_u(F_n^3) < \infty$. Denote by V_n^3 the finely interior of F_n^3 . Since the killing measure $K(dx) = N(x, \Delta)\mu_H(dx)$ is a smooth measure, there exists an \mathcal{E} -nest $\{F_n^4\}$ of compact subsets of E such that $K(F_n^4) < \infty$. Denote by V_n^4 the finely interior of F_n^4 . Define $V'_n = V_n^1 \cap V_n^2 \cap V_n^3 \cap V_n^4$. Then $\{V'_n\} \in \Theta$, each u_n is bounded on V'_n , and

$$\begin{aligned} & \int_{V'_n} \int_{E_\Delta} (\tilde{u}(x) - \tilde{u}(y))^2 N(x, dy) \mu_H(dx) \\ &= \int_{V'_n} \int_E (\tilde{u}(x) - \tilde{u}(y))^2 J(dy, dx) + \int_{V'_n} \tilde{u}^2(x) K(dx) \\ &< \infty. \end{aligned}$$

To simplify notation, we still use V_n to denote $V_n \cap V'_n$.

For $n \in \mathbb{N}$, we define $E_n = \{x \in E \mid \widetilde{h_n}(x) > \frac{1}{n}\}$, where $h_n := G_1^{V_n} \phi$. Then $\{E_n\} \in \Theta$ satisfying $\overline{E_n}^\mathcal{E} \subset E_{n+1}$ \mathcal{E} -q.e. and $E_n \subset V_n$ \mathcal{E} -q.e. for each $n \in \mathbb{N}$ (cf. [12, Lemma 3.8]). Here $\overline{E_n}^\mathcal{E}$ denotes the \mathcal{E} -quasi-closure of E_n . Define $f_n = n\widetilde{h_n} \wedge 1$. Then $f_n = 1$ on E_n and $f_n = 0$ on V_n^c . Since f_n is a 1-excessive function of $(\mathcal{E}^{V_n}, D(\mathcal{E})_{V_n})$ and $f_n \leq n\widetilde{h_n} \in D(\mathcal{E})_{V_n}$, hence $f_n \in D(\mathcal{E})_{V_n}$ by [17, Remark 3.4(ii)]. Denote by Q_n the bound of $|u_n|$ on V_n . Then $u_n f_n = ((-Q_n) \vee u_n \wedge Q_n) f_n \in D(\mathcal{E})_{V_n, b}$. For $n \in \mathbb{N}$, we denote by $\{\mathcal{F}_t^n\}$ the minimum completed admissible filtration of X^{V_n} . For $n < l$, $\mathcal{F}_t^n \subset \mathcal{F}_t^l \subset \mathcal{F}_t$. Since $E_n \subset V_n$, τ_{E_n} is an $\{\mathcal{F}_t^n\}$ -stopping time.

Lemma 2.13. ([11, Lemma 25.3]) *For any optional time T and predictable process Y , the random variable $Y_T 1_{(T < \infty)} \in \mathcal{F}_{T-}$.*

Hereafter for a martingale M , we denote by M^c and M^d its continuous part and purely discontinuous part, respectively.

Lemma 2.14. *For $n < l$, we have $M_{t \wedge \tau_{E_n}}^{n, [u_n f_n], c} = M_{t \wedge \tau_{E_n}}^{l, [u_l f_l], c}$, $t \geq 0$, P_x -a.s. for \mathcal{E} -q.e. $x \in V_n$.*

Proof. Let $n < l$. Since $M^{n, [u_n f_n]} \in \dot{\mathcal{M}}^{V_n}$, $M^{n, [u_n f_n]}$ is an $\{\mathcal{F}_t^n\}$ -martingale by the Markov property. Since τ_{E_n} is an $\{\mathcal{F}_t^n\}$ -stopping time, $\{M_{t \wedge \tau_{E_n}}^{n, [u_n f_n]}\}$ is an $\{\mathcal{F}_{t \wedge \tau_{E_n}}^n\}$ -martingale. Denote $\Upsilon_t^n = \sigma\{X_{s \wedge \tau_{E_n}}^{V_n} \mid 0 \leq s \leq t\}$. Then $\{M_{t \wedge \tau_{E_n}}^{n, [u_n f_n], c}\}$ is a $\{\Upsilon_t^n\}$ -martingale. Denote $\Upsilon_t^{n, l} = \sigma\{X_{s \wedge \tau_{E_n}}^{V_l} \mid 0 \leq s \leq t\}$. Similarly, we can show that $\{M_{t \wedge \tau_{E_n}}^{l, [u_n f_n], c}\}$ is a $\{\Upsilon_t^{n, l}\}$ -martingale. Since

$$X_s^{V_l} = X_s = X_s^{V_n}, \quad s < \tau_{E_n}, \quad P_x\text{-a.s. for } \mathcal{E}\text{-q.e. } x \in V_n, \quad (2.5)$$

we find that $\Upsilon_{t-}^n = \Upsilon_{t-}^{n, l}$. Hence $\{M_{t \wedge \tau_{E_n}}^{l, [u_n f_n], c}\} \in \Upsilon_{t-}^{n, l}$ by Lemma 2.13 and therefore $\{M_{t \wedge \tau_{E_n}}^{l, [u_n f_n], c}\}$ is a $\{\Upsilon_t^n\}$ -martingale. Moreover, $N_{t \wedge \tau_{E_n}}^{l, [u_n f_n]} \in \Upsilon_{t-}^{n, l} = \Upsilon_{t-}^n \subset \mathcal{F}_{t \wedge \tau_{E_n}}^n$.

Let $N \in \mathcal{N}_c^{V_j}$ for some $j \in \mathbb{N}$. Then, for any $T > 0$,

$$\begin{aligned} \sum_{k=1}^{[rT]} E_{\bar{h}_j \cdot m}[(N_{\frac{k+1}{r}} - N_{\frac{k}{r}})^2] &\leq \sum_{k=1}^{[rT]} e^T(E(N_{\frac{1}{r}}^2), e^{-\frac{k}{r}} \hat{T}_{\frac{k}{r}}^{V_j} \bar{h}_j) \\ &\leq \sum_{k=1}^{[rT]} e^T(E(N_{\frac{1}{r}}^2), \bar{h}_j) \\ &\leq rT e^T E_{\bar{h}_j \cdot m}(N_{\frac{1}{r}}^2) \rightarrow 0 \quad \text{as } r \rightarrow \infty. \end{aligned}$$

Hence

$$\sum_{k=1}^{[rT]} (N_{\frac{k+1}{r}} - N_{\frac{k}{r}})^2 \rightarrow 0 \quad \text{in } P_m \quad \text{as } r \rightarrow \infty,$$

which implies that the quadratic variation process of N w.r.t. P_m is 0. Therefore, the quadratic variation processes of $\{N_{t \wedge \tau_{E_n}}^{l, [u_n f_n]}\}$ and $\{N_{t \wedge \tau_{E_n}}^{n, [u_n f_n]}\}$ w.r.t. P_m are 0.

By [12, Proposition 3.3], $(\widehat{G_1 \phi})_{V_n^c}^1 = \hat{G}_1 \phi - \hat{G}_1^{V_n} \phi$. Since $V_n^c \supset V_l^c$, $(\widehat{G_1 \phi})_{V_n^c}^1 \geq (\widehat{G_1 \phi})_{V_l^c}^1$. Then $\hat{G}_1^{V_n} \phi \leq \hat{G}_1^{V_l} \phi$ and thus

$$\bar{h}_n \leq \bar{h}_l. \quad (2.6)$$

Therefore

$$e^{V_n}(A) \leq e^{V_l}(A) \quad (2.7)$$

for any AF $A = (A_t)_{t \geq 0}$ of X^{V_n} .

By (2.5), we find that for \mathcal{E} -q.e. $x \in V_n$,

$$\begin{aligned} M_{t \wedge \tau_{E_n}}^{n, [u_n f_n], c} + M_{t \wedge \tau_{E_n}}^{n, [u_n f_n], d} + N_{t \wedge \tau_{E_n}}^{n, [u_n f_n]} \\ = \widetilde{u_n f_n}(X_{t \wedge \tau_{E_n}}^{V_n}) - \widetilde{u_n f_n}(X_0^{V_n}) \\ = \widetilde{u_n f_n}(X_{t \wedge \tau_{E_n}}^{V_l}) - \widetilde{u_n f_n}(X_0^{V_l}) \\ = M_{t \wedge \tau_{E_n}}^{l, [u_n f_n], c} + M_{t \wedge \tau_{E_n}}^{l, [u_n f_n], d} + N_{t \wedge \tau_{E_n}}^{l, [u_n f_n]}, \quad P_x - a.s. \end{aligned}$$

Then $\{M_{t \wedge \tau_{E_n}}^{n, [u_n f_n], d}\} \in \Upsilon_t^n$, and $\{M_{t \wedge \tau_{E_n}}^{n, [u_n f_n]}\}$ and $\{M_{t \wedge \tau_{E_n}}^{l, [u_n f_n]}\}$ are $\{\Upsilon_t^n\}$ -martingales. Hence $M_{t \wedge \tau_{E_n}}^{n, [u_n f_n], c} = M_{t \wedge \tau_{E_n}}^{l, [u_n f_n], c}$ and $N_{t \wedge \tau_{E_n}}^{n, [u_n f_n]} = N_{t \wedge \tau_{E_n}}^{l, [u_n f_n]}$, P_x -a.s. for m -a.e. $x \in V_n$. This implies that $E_m(< M_{t \wedge \tau_{E_n}}^{n, [u_n f_n], c} - M_{t \wedge \tau_{E_n}}^{l, [u_n f_n], c} >_t) = 0$, $\forall t \geq 0$. By Theorem [14, Theorem 5.8(i)], we find that $M_{t \wedge \tau_{E_n}}^{n, [u_n f_n], c} = M_{t \wedge \tau_{E_n}}^{l, [u_n f_n], c}$, $\forall t \geq 0$, P_x -a.s. for \mathcal{E} -q.e. $x \in V_n$.

Since $u_n f_n = u_l f_l = u$ on E_n , similar to [13, Lemma 2.4], we can show that $M_t^{l, [u_n f_n], c} = M_t^{l, [u_l f_l], c}$ when $t < \tau_{E_n}$, P_x -a.s. for \mathcal{E} -q.e. $x \in V_l$. Then $M_{t \wedge \tau_{E_n}}^{l, [u_n f_n], c} = M_{t \wedge \tau_{E_n}}^{l, [u_l f_l], c}$, $t \geq 0$, P_x -a.s. for \mathcal{E} -q.e. $x \in V_l$. Therefore $M_{t \wedge \tau_{E_n}}^{n, [u_n f_n], c} = M_{t \wedge \tau_{E_n}}^{l, [u_l f_l], c}$, $t \geq 0$, P_x -a.s. for \mathcal{E} -q.e. $x \in V_n$. \square

Proof of Theorem 2.4 (a) Suppose that u satisfies Condition (S). We shall show that u admits the Fukushima type decomposition (2.2).

We define $M_{t \wedge \tau_{E_n}}^{[u],c} := \lim_{l \rightarrow \infty} M_{t \wedge \tau_{E_n}}^{l,[uf_l],c}$ and $M_t^{[u],c} := 0$ for $t > \zeta$ if there exists some n such that $\tau_{E_n} = \zeta$ and $\zeta < \infty$; or $M_t^{[u],c} := 0$ for $t \geq \zeta$, otherwise. By Lemma 2.14, $M^{[u],c}$ is well defined. Define $M_t^n := M_{t \wedge \tau_{E_n}}^{n+1,[uf_{n+1}],c}$ for $t \geq 0$ and $n \in \mathbb{N}$. Then $M_{t \wedge \tau_{E_n}}^{[u],c} = M_{t \wedge \tau_{E_n}}^n$ P_x -a.s. for \mathcal{E} -q.e. $x \in V_{n+1}$ by Lemma 2.14. Since $\overline{E}_n^\mathcal{E} \subset E_{n+1} \subset V_{n+1}$ \mathcal{E} -q.e. implies that $P_x(\tau_{E_n} = 0) = 1$ for $x \notin V_{n+1}$, $M_{t \wedge \tau_{E_n}}^{[u],c} = M_{t \wedge \tau_{E_n}}^n$ P_x -a.s. for \mathcal{E} -q.e. $x \in E$. Similar to (2.6) and (2.7), we can show that $e^{V_n}(M^n) \leq e^{V_{n+1}}(M^n)$ for each $n \in \mathbb{N}$. Then $M^n \in \dot{\mathcal{M}}^{V_n}$ and hence $M^{[u],c} \in \dot{\mathcal{M}}_{loc}$.

Next we show that M^n is also an $\{\mathcal{F}_t\}$ -martingale. In fact, by the fact that τ_{E_n} is an $\{\mathcal{F}_t^{n+1}\}$ -stopping time, we find that $I_{\tau_{E_n} \leq s}$ is $\mathcal{F}_{s \wedge \tau_{E_n}}^{n+1}$ -measurable for any $s \geq 0$. Let $0 \leq s_1 < \dots < s_k \leq s < t$ and $g \in \mathcal{B}_b(\mathbb{R}^k)$. Then, we obtain by the fact $M^{n+1,[uf_{n+1}],c} \in \dot{\mathcal{M}}^{V_{n+1}}$ that for \mathcal{E} -q.e. $x \in V_{n+1}$,

$$\begin{aligned} & \int_{\Omega} M_t^n g(X_{s_1}, \dots, X_{s_k}) dP_x \\ &= \int_{\tau_{E_n} \leq s} M_t^n g(X_{s_1}, \dots, X_{s_k}) dP_x + \int_{\tau_{E_n} > s} M_t^n g(X_{s_1}, \dots, X_{s_k}) dP_x \\ &= \int_{\tau_{E_n} \leq s} M_s^n g(X_{s_1}, \dots, X_{s_k}) dP_x \\ & \quad + \int_{\Omega} M_{t \wedge \tau_{E_n}}^{n+1,[uf_{n+1}],c} g(X_{s_1 \wedge \tau_{E_n}}^{V_{n+1}}, \dots, X_{s_k \wedge \tau_{E_n}}^{V_{n+1}}) I_{\tau_{E_n} > s} dP_x \\ &= \int_{\tau_{E_n} \leq s} M_s^n g(X_{s_1}, \dots, X_{s_k}) dP_x \\ & \quad + \int_{\Omega} M_{s \wedge \tau_{E_n}}^{n+1,[uf_{n+1}],c} g(X_{s_1 \wedge \tau_{E_n}}^{V_{n+1}}, \dots, X_{s_k \wedge \tau_{E_n}}^{V_{n+1}}) I_{\tau_{E_n} > s} dP_x \\ &= \int_{\tau_{E_n} \leq s} M_s^n g(X_{s_1}, \dots, X_{s_k}) dP_x + \int_{\tau_{E_n} > s} M_s^n g(X_{s_1}, \dots, X_{s_k}) dP_x \\ &= \int_{\Omega} M_s^n g(X_{s_1}, \dots, X_{s_k}) dP_x. \end{aligned}$$

Obviously, the equality holds for $x \notin V_{n+1}$. Hence M^n is an $\{\mathcal{F}_t\}$ -martingale. By Proposition 3.4 below, $\cup_n [0, \tau_{E_n}] \supseteq I(\zeta)$ P_x -a.s. for \mathcal{E} -q.e. $x \in E$. Therefore $M^{[u],c} \in \dot{\mathcal{M}}_{loc}^{I(\zeta)}$.

We define $\phi(x, y) = \tilde{u}(y) - \tilde{u}(x)$, $\phi_l(x, y) = (\tilde{u}(y) - \tilde{u}(x))1_{\{|\tilde{u}(x) - \tilde{u}(y)| > \frac{1}{l}\}}$, and

$$M_t^l := \sum_{0 \leq s \leq t} \phi_l(X_{s-}, X_s) - \int_0^t \int_{E_{\Delta}} \phi_l(X_s, y) N(X_s, dy) dH_s$$

for $l \in \mathbb{N}$. Denote $T_m^l := \inf\{t > 0 \mid |M_t^l| \geq m\}$ for $m \in \mathbb{N}$. Then, $\{T_m^l\}$ is an

$\{\mathcal{F}_t\}$ -stopping time and

$$\begin{aligned} |M_{t \wedge T_m^l \wedge \tau_{E_n}}^l| &\leq |M_{t \wedge T_m^l \wedge \tau_{E_n}}^l - \phi(X_{t \wedge T_m^l \wedge \tau_{E_n}-}, X_{t \wedge T_m^l \wedge \tau_{E_n}})| \\ &\leq m + |\phi(X_{t \wedge T_m^l \wedge \tau_{E_n}-}, X_{t \wedge T_m^l \wedge \tau_{E_n}})|. \end{aligned}$$

We define (cf. [14, Theorem 5.3])

$$\hat{S}_{00}^* := \{\mu \in S_0 \mid \hat{U}_1 \mu \leq c \hat{G}_1 \phi \text{ for some constant } c > 0\}.$$

Let $\nu \in S_{00}^*$ satisfying $\nu(E) < \infty$. Then, by [14, Lemma 5.9], we get

$$\begin{aligned} E_\nu[(M_{t \wedge T_m^l \wedge \tau_{E_n}}^l)^2] &\leq 2m^2\nu(E) + 2E_\nu \left[\sum_{s \leq t \wedge \tau_{E_n}} \phi^2(X_{s-}, X_s) \right] \\ &= 2m^2\nu(E) + 2E_\nu \left[\int_0^{t \wedge \tau_{E_n}} \int_{E_\Delta} \phi^2(X_s, y) N(X_s, dy) dH_s \right] \\ &\leq 2m^2\nu(E) + 2C_\nu(1+t) \int_{E_n} \tilde{h} \int_{E_\Delta} \phi^2(x, y) N(x, dy) \mu_H(dx) \\ &< \infty, \end{aligned}$$

where C_ν is a positive constant. Hence, for fixed n and m , $t \rightarrow M_{t \wedge T_m^l \wedge \tau_{E_n}}^l$ is a square integrable purely discontinuous P_ν -martingale. By [6, Corollary A.3.1], we find that

$$(M_{t \wedge T_m^l \wedge \tau_{E_n}}^l)^2 - \sum_{s \leq t} (\Delta M_{s \wedge T_m^l \wedge \tau_{E_n}}^l)^2 = (M_{t \wedge T_m^l \wedge \tau_{E_n}}^l)^2 - \sum_{s \leq t \wedge T_m^l \wedge \tau_{E_n}} \phi_l^2(X_{s-}, X_s)$$

is a P_ν -martingale, which implies that

$$\begin{aligned} E_\nu[(M_{t \wedge \tau_{E_n}}^l)^2] &\leq \liminf_{m \rightarrow \infty} E_\nu[(M_{t \wedge T_m^l \wedge \tau_{E_n}}^l)^2] \\ &= \liminf_{m \rightarrow \infty} E_\nu \left[\sum_{s \leq t \wedge T_m^l \wedge \tau_{E_n}} \phi_l^2(X_{s-}, X_s) \right] \\ &= E_\nu \left[\sum_{s \leq t \wedge \tau_{E_n}} \phi_l^2(X_{s-}, X_s) \right] \\ &\leq E_\nu \left[\int_0^{t \wedge \tau_{E_n}} \int_{E_\Delta} \phi^2(X_s, y) N(X_s, dy) dH_s \right] \\ &\leq C_\nu(1+t) \int_{E_n} \tilde{h}(x) \int_{E_\Delta} \phi^2(x, y) N(x, dy) \mu_H(dx) \\ &< \infty. \end{aligned}$$

Thus $\{M_{t \wedge \tau_{E_n}}^l\}$ is a P_ν -square-integrable martingale. Since $\{M_{t \wedge T_m^l \wedge \tau_{E_n}}^l\}_{m=1}^\infty$ is $L^2(P_\nu)$ -bounded, by virtue of Banach-Saks theorem, we obtain that

$$E_\nu[(M_{t \wedge \tau_{E_n}}^l)^2] = E_\nu \left[\int_0^{t \wedge \tau_{E_n}} \int_{E_\Delta} \phi_l^2(X_s, y) N(X_s, dy) dH_s \right].$$

By Doob's maximum inequality, we obtain that for any $\alpha > 0$ and l, k ,

$$\begin{aligned} P_\nu \left(\sup_{0 \leq s \leq T} |M_{s \wedge \tau_{E_n}}^l - M_{s \wedge \tau_{E_n}}^k| > \alpha \right) \\ \leq \frac{4C_\nu(1+T)}{\alpha^2} \int_{E_n} \tilde{h}(x) \int_{E_\Delta} (\phi_l - \phi_k)^2(x, y) N(x, dy) \mu_H(dx). \end{aligned}$$

By the diagonal method, we may select a subsequence $l_k \rightarrow \infty$ such that for each n when $k \geq n$,

$$\int_{E_n} \tilde{h}(x) \int_{E_\Delta} (\phi_{l_{k+1}} - \phi_{l_k})^2(x, y) N(x, dy) \mu_H(dx) \leq \frac{1}{2^{3k}}.$$

Then

$$P_\nu \left(\sup_{0 \leq s \leq T} |M_{s \wedge \tau_{E_n}}^{l_{k+1}} - M_{s \wedge \tau_{E_n}}^{l_k}| > \frac{1}{2^k} \right) \leq \frac{C_\nu(1+T)}{2^k}.$$

Define $\Lambda_0^n = \{\omega \in \Omega \mid M_{s \wedge \tau_{E_n}}^{l_k} \text{ converges uniformly in } s \text{ on each finite interval}\}$. Then, $\Lambda_0^{n_1} \supset \Lambda_0^{n_2}$ for $n_1 \leq n_2$. By the Borel-Cantelli lemma, we get

$$P_\nu((\Lambda_0^n)^c) = 0 \text{ for } \nu \in \hat{S}_{00}^* \text{ with } \nu(E) < \infty.$$

Therefore $P_x((\Lambda_0^n)^c) = 0$ for \mathcal{E} -q.e. $x \in E$ (cf. [14, Theorem A.3]). Let Γ_k be the defining set of the MAF M^{l_k} , denote $\Gamma = \cap_k \Gamma_k$ and $\Lambda^n = \Lambda_0^n \cap \Gamma$. Then we have $P_x((\Lambda^n)^c) = 0$ for \mathcal{E} -q.e. $x \in E$. For each $\omega \in \Lambda^n$, $M_{t \wedge \tau_{E_n}}^{l_k}$ converges uniformly in t on each finite interval and for each k ,

$$M_{(t+s) \wedge \tau_{E_n}}^{l_k} = M_{t \wedge \tau_{E_n}}^{l_k} + M_{s \wedge \tau_{E_n}}^{l_k} \circ \theta_{t \wedge \tau_{E_n}}, \text{ if } 0 \leq t, s < \infty.$$

Thus, L^n , the limit of $\{M_{s \wedge \tau_{E_n}}^{l_k}\}_{k=1}^\infty$, is a P_x -square integrable purely discontinuous martingale for \mathcal{E} -q.e. $x \in E$ and satisfies:

$$L_{(t+s) \wedge \tau_{E_n}}^n = L_{t \wedge \tau_{E_n}}^n + L_{s \wedge \tau_{E_n}}^n \circ \theta_{t \wedge \tau_{E_n}}, \text{ if } 0 \leq t, s < \infty.$$

By the above construction, we find that $L_{t \wedge \tau_{E_{n_1}}}^{n_1} = L_{t \wedge \tau_{E_{n_1}}}^{n_2}$ for $n_1 \leq n_2$. We define $M_t^{[u],d} = L_t^n, t \leq \tau_{E_n}$, and $M_t^{[u],d} = L_t^n, t \geq \zeta$, if for some n , $\tau_{E_n} = \zeta < \infty$; $M_t^{[u],d} = 0, t \geq \zeta$, otherwise. Then $M^{[u],d} \in \mathcal{M}_{loc}^{I(\zeta)}$, which gives all the jumps of $\tilde{u}(X_t) - \tilde{u}(X_0)$ on $I(\zeta)$. Since $\{M_t^l\}$ is an MAF for each l , we find that $\{M_t^{[u],d}\}$ is a local MAF by the uniform convergence on $I(\zeta)$.

We define $N_{t \wedge \tau_{E_n}}^{[u]} := \tilde{u}(X_{t \wedge \tau_{E_n}}) - \tilde{u}(X_0) - M_{t \wedge \tau_{E_n}}^{[u],c} - M_{t \wedge \tau_{E_n}}^{[u],d}$ for each $n \in \mathbb{N}$. Then $N^{[u]}$ is a local AF of \mathbf{M} and $t \rightarrow N_{t \wedge \tau_{E_n}}^{[u]}$ is continuous. Now we show that the quadratic variation process of $N^{[u]}$ is zero and hence $N^{[u]} \in \mathcal{L}_c$. By Fukushima's decomposition for part processes, we have that for $k > n$,

$$\begin{aligned} \widetilde{u_k f_k}(X_{t \wedge \tau_{E_n}}) - \widetilde{u_k f_k}(X_0) &= \widetilde{u_k f_k}(X_{t \wedge \tau_{E_n}}^{V_k}) - \widetilde{u_k f_k}(X_0^{V_k}) \\ &= M_{t \wedge \tau_{E_n}}^{k,[u_k f_k]} + N_{t \wedge \tau_{E_n}}^{k,[u_k f_k]} \\ &= M_{t \wedge \tau_{E_n}}^{k,[u_k f_k],c} + M_{t \wedge \tau_{E_n}}^{k,[u_k f_k],d} + N_{t \wedge \tau_{E_n}}^{k,[u_k f_k]} \end{aligned}$$

and

$$\tilde{u}(X_{t \wedge \tau_{E_n}}) - \tilde{u}(X_0) = M_{t \wedge \tau_{E_n}}^{[u],c} + M_{t \wedge \tau_{E_n}}^{[u],d} + N_{t \wedge \tau_{E_n}}^{[u]}.$$

Then

$$\begin{aligned} N_{t \wedge \tau_{E_n}}^{[u]} &= N_{t \wedge \tau_{E_n}}^{k,[u_k f_k]} + M_{t \wedge \tau_{E_n}}^{k,[u_k f_k],d} - M_{t \wedge \tau_{E_n}}^{[u],d} + \tilde{u}(X_{t \wedge \tau_{E_n}}) - \widetilde{u_k f_k}(X_{t \wedge \tau_{E_n}}) \\ &= N_{t \wedge \tau_{E_n}}^{k,[u_k f_k]} + M_{t \wedge \tau_{E_n}}^{k,[u_k f_k],d} - M_{t \wedge \tau_{E_n}}^{[u],d} + [\tilde{u}(X_{\tau_{E_n}}) - \widetilde{u_k f_k}(X_{\tau_{E_n}})]1_{\{\tau_{E_n} \leq t\}}. \end{aligned}$$

Define $A_t := [\tilde{u}(X_{\tau_{E_n}}) - \widetilde{u_k f_k}(X_{\tau_{E_n}})]1_{\{\tau_{E_n} \leq t\}}$. Since both $\{M_{t \wedge \tau_{E_n}}^{k,[u_k f_k],d}\}$ and $\{M_{t \wedge \tau_{E_n}}^{[u],d}\}$ are $\{\mathcal{F}_{t \wedge \tau_{E_n}}\}$ -purely discontinuous martingales, τ_{E_n} is an $\{\mathcal{F}_{t \wedge \tau_{E_n}}\}$ -stopping time, and $\tilde{u}(X_\zeta) = \widetilde{u_k f_k}(X_\zeta) = 0$, we find that $\{A_t\}$ is an adapted quasi-left continuous bounded variation processes. Denote by $\{A_t^p\}$ the dual predictable projection of A . Then $\{A_t^p\}$ is an adapted continuous bounded variation processes (cf. [6, Theorem A.3.5]). Note that

$$N_{t \wedge \tau_{E_n}}^{[u]} = N_{t \wedge \tau_{E_n}}^{k,[u_k f_k]} + (M_{t \wedge \tau_{E_n}}^{k,[u_k f_k],d} - M_{t \wedge \tau_{E_n}}^{[u],d} + A_t - A_t^p) + A_t^p.$$

Hence $M_{t \wedge \tau_{E_n}}^{k,[u_k f_k],d} - M_{t \wedge \tau_{E_n}}^{[u],d} + A_t - A_t^p$ is a purely discontinuous martingale with zero jump, which must be equal to zero. Consequently, $N_{t \wedge \tau_{E_n}}^{[u]}$ has zero quadratic variation w.r.t. P_x for \mathcal{E} -q.e. $x \in E$.

Finally, we prove the uniqueness of decomposition (2.2). Suppose that $M^1 \in \mathcal{M}_{loc}^{I(\zeta)}$ and $N^1 \in \mathcal{L}_c$ such that

$$\tilde{u}(X_t) - \tilde{u}(X_0) = M_t^1 + N_t^1, \quad t \geq 0, \quad P_x\text{-a.s. for } \mathcal{E}\text{-q.e. } x \in E.$$

By Proposition 3.4 below, we can choose an $\{E_n\} \in \Theta$ such that $I(\zeta) = \cup_n [0, \tau_{E_n}]$ P_x -a.s. for \mathcal{E} -q.e. $x \in E$. Then, for each $n \in \mathbb{N}$, $\{(M^{[u]} - M^1)^{\tau_{E_n}}\}$ is a locally square integrable martingale and a zero quadratic variation process w.r.t. P_m . This implies that $P_m(< (M^{[u]} - M^1)^{\tau_{E_n}} >_t = 0, \forall t \in [0, \infty)) = 0$. Consequently by the analog of [6, Lemma 5.1.10] in the semi-Dirichlet forms setting, $P_x(< (M^{[u]} - M^1)^{\tau_{E_n}} >_t = 0, \forall t \in [0, \infty)) = 0$ for \mathcal{E} -q.e. $x \in E$. Therefore $M_t^{[u]} = M_t^1$, $0 \leq t \leq \tau_{E_n}$, P_x -a.s. for \mathcal{E} -q.e. $x \in E$. Since n is arbitrary, we obtain the uniqueness of decomposition (2.2) up to the equivalence of local AFs.

(b) Let $u \in D(\mathcal{E})_{loc}$ and suppose that the decomposition (2.2) holds. We shall show that u satisfies Condition (S). First, $M^{[u],d} \in \mathcal{M}_{loc}^{d,I(\zeta)}$ implies that there exist a sequence of increasing stopping times $\{T_n\}$ such that $\cup_n [0, T_n] = I(\zeta)$ and a sequence of L^2 -martingales $\{M^n\}$ such that $(M^{[u],d} 1_{I(\zeta)})^{T_n} = (M^n 1_{I(\zeta)})^{T_n}$. Hence $(M^{[u],d})^{T_n}$ is an L^2 -martingale and its square bracket equals $\sum_{0 < s \leq t \wedge T_n} (u(X_s) - u(X_{s-}))^2$ and is a integrable increasing process. We use $[M^{[u],d}](t, \omega)$ to denote $(\sum_{0 < s \leq t} (u(X_s(w)) - u(X_{s-}(w)))^2) 1_{I(\zeta)}(t, w)$. Then, $[M^{[u],d}] \in (\mathcal{A}_{loc,0})^{I(\zeta)}$ (cf. [9, §8.3]) and is a local AF. Therefore $< M^{[u],d} >_t = (\int_0^t \int_{E_\Delta} (\tilde{u}(X_s) - \tilde{u}(y))^2 N(X_s, dy) dH_s) 1_{I(\zeta)}$ is a PCAF on $I(\zeta)$ and can be extended to a PCAF by [2, Remark 2.2]. By Proposition 2.1, its Revuz measure $\mu'_u(dx) = \int_{E_\Delta} (\tilde{u}(x) - \tilde{u}(y))^2 N(x, dy) \mu_H(dx)$ is a smooth measure. Thus $\mu_u(dx) = \int_E (\tilde{u}(x) - \tilde{u}(y))^2 J(dy, dx)$, which is controlled by $\mu'_u(dx)$, is also a smooth measure. This implies that u satisfies Condition (S). \square

3 Remarks on stochastic sets of interval type

For the convenience of the reader, we recall first some concepts and results concerning sets of interval type given in [9, §8.3]. Let (Ω, \mathcal{F}, P) be a complete probability space with a filtration $\{\mathcal{F}_t\}$ satisfying the usual condition. A subset $B \subset \Omega \times [0, \infty)$ is said to be a set of interval type if there exists a nonnegative random variable T such that for each $\omega \in \Omega$, the section B_ω is either $[0, T(\omega)[$ or $[0, T(\omega)]$ and $B_\omega \neq \emptyset$. B is called an optional (resp. predictable) set of interval type, if it is an optional (resp. predictable) set and is of interval type.

Let B be an optional set of interval type. A stochastic process Y defined on B is called a special semi-martingale on B , denoted by $(\mathcal{S}_p)^B$, if there exist a sequence of increasing stopping times $\{T_n\}$ with $T_n \uparrow T$ (T is the debut of B^c), and a sequence of special semi-martingales $\{Y^n\}$ such that, $\cup_n \llbracket 0, T_n \rrbracket \supset B$ and for each n and $t > 0$, $(Y1_B)_{t \wedge T_n} = (Y^n 1_B)_{t \wedge T_n}$. In the same manner one can define local martingale on B (denoted by $(\mathcal{M}_{loc})^B$), adapted process with locally integrable variation on B (denoted by $(\mathcal{A}_{loc})^B$), and others (cf. [9, Definition 8.19]).

The assertion below, which is referred as Doob-Meyer decomposition on sets of interval type, was stated in [9, Theorem 8.26].

Assertion. Let B be an optional set of interval type and $Y \in (\mathcal{S}_p)^B$. Then Y can be uniquely decomposed as: $Y = M + A$, where $M \in (\mathcal{M}_{loc})^B$ and $A \in (\mathcal{A}_{loc,0})^B$ is a predictable process (i.e., A is the restriction of a predictable process on B).

Although the above assertion has been employed by several papers (including our previous paper [14]), during the course of our research we observed the following remark.

Remark 3.1. *In the above assertion if B is not a predictable set of interval type, then the uniqueness of the decomposition $Y = M + A$ may fail to be true.*

Proof. We take just the counterexample stated in [9, Remark 8.24] to illustrate our remark. Let $T > 0$ be a totally inaccessible time with $P(T < \infty) > 0$, e.g., the first jump time of a Poisson process. We consider the stochastic interval $B = \llbracket 0, T \rrbracket$. Then B is an optional set of interval type but not a predictable set. Let $A_t := 1_{\llbracket T, \infty \rrbracket}(t)$ and \tilde{A}_t be its dual predictable projection. Let $\{Y_t, 0 \leq t < T\}$ be the restriction of \tilde{A} on B . Then we have decomposition $Y = M + 0$ where $M \in (\mathcal{M}_{loc})^B$ is the restriction of $\tilde{A} - A$ on B . But we have also another decomposition $Y = 0 + Y$ where $Y \in (\mathcal{A}_{loc,0})^B$ is the restriction of \tilde{A} on B . Therefore the decomposition stated in the above assertion is not unique. \square

The above remark reveals that Doob-Meyer decomposition may fail to be unique on an optional set of interval type. In the same manner, we observe that the Fukushima type decomposition may fail to be unique on an optional set of interval type. Note that with the notation of Theorem 2.4, $\llbracket 0, \zeta \rrbracket$ is an optional set of interval type but is not necessarily a predictable set.

Remark 3.2. In Theorem 2.4 if we use $\mathcal{M}_{loc}^{[0, \zeta]}$ instead of $\mathcal{M}_{loc}^{I(\zeta)}$, then the uniqueness of the decomposition may fail to be true.

Proof. We provide below a counterexample to illustrate the remark. Suppose that we have a decomposition

$$\tilde{u}(X_t) - \tilde{u}(X_0) = M_t^{[u]} + N_t^{[u]}, \quad t \geq 0, \quad P_x\text{-a.s. for } \mathcal{E}\text{-q.e. } x \in E,$$

with $M^{[u]} \in \mathcal{M}_{loc}^{[0, \zeta]}$ and $N^{[u]} \in \mathcal{L}_c$, and suppose that $\zeta_i = \zeta$ with $P_x(\zeta < \infty) > 0$ P_x -a.s. for \mathcal{E} -q.e. $x \in E$. We write $B_t := 1_{\{\zeta \leq t\}}$ (i.e. $B_t = I_\Delta(X_t)$) and denote by \tilde{B}_t the dual predictable projection of B_t . Define $A_t := \tilde{B}_t 1_{\{0 \leq t < \zeta\}}$. Then it is clear that $A \in \mathcal{L}_c$. But we have also $A \in (\mathcal{M}_{loc})^{[0, \zeta]}$, because $\{A 1_{[0, \zeta]}\}^\zeta = \{(\tilde{B} - B) 1_{[0, \zeta]}\}^\zeta$. Therefore, we have another decomposition:

$$\tilde{u}(X_t) - \tilde{u}(X_0) = (M_t^{[u]} - A_t) + (N_t^{[u]} + A_t), \quad t \geq 0, \quad P_x\text{-a.s. for } \mathcal{E}\text{-q.e. } x \in E,$$

which violates the uniqueness. \square

With the above discussion, we see that the existence of a suitable predictable set of interval type is important for the uniqueness of the Fukushima type decomposition. Fortunately in Theorem 2.4 we find such a suitable set $I(\zeta) := [0, \zeta \cup \{\zeta_i\}]$. In Proposition 3.4 below we shall provide a proof for the existence and uniqueness of such ζ_i . We shall need the following characterizations for a set of interval type to be predictable. For their proofs we refer to [9].

Lemma 3.3. ([9, Theorems 8.18]) *The following statements are equivalent:*

- (i) B is a predictable set of interval type.
- (ii) $1_B = 1_F 1_{[0, T]} + 1_{F^c} 1_{[0, T]}$, where T is a stopping time, $F \in \mathcal{F}_{T-}$ and $T_F > 0$ is a predictable time.
- (iii) $B = \cup_n [0, T_n]$, where $\{T_n\}$ is an increasing sequence of stopping times.

Below we consider a quasi-regular semi-Dirichlet form $(\mathcal{E}, D(\mathcal{E}))$ on $L^2(E; m)$. Let $\mathbf{M} = (\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, (X_t)_{t \geq 0}, (P_x)_{x \in E_\Delta})$ with lifetime ζ be the associated m -tight special standard process.

Proposition 3.4. (i) *There exists an $\{\mathcal{F}_t\}$ -stopping time ζ_i (may be identically equal to ∞) which is the totally inaccessible part of ζ w.r.t. P_x for \mathcal{E} -q.e. $x \in E$. Such a ζ_i is unique in the sense of P_x -a.s. for \mathcal{E} -q.e. $x \in E$.*

(ii) *Denote by $I(\zeta) := [0, \zeta \cup \{\zeta_i\}]$. Then $I(\zeta)$ is a predictable set of interval type, and there exists a sequence $\{V_n\} \in \Theta$ such that for any $\{U_n\} \in \Theta$, $I(\zeta) = \cup_n [0, \tau_{V_n \cap U_n}]$ P_x -a.s. for \mathcal{E} -q.e. $x \in E$.*

Proof. The uniqueness of ζ_i follows from [9, Theorem 4.20]. Below we show the existence of ζ_i and the assertion (ii). By the local compactification method (cf. [10,

Theorem 3.5], see also [16, Theorem VI.1.6]) in the semi-Dirichlet forms setting, we may assume without loss of generality that $(X_t)_{t \geq 0}$ is a Hunt process and E is a locally compact separable metric space.

We take a fixed sequence $\{V_n\} \in \Theta$ such that each V_n is a relatively compact open set and $E = \cup_n V_n$. Denote by $B := \cup_n \llbracket 0, \tau_{V_n} \rrbracket$ and $T := \lim_{n \rightarrow \infty} \tau_{V_n}$. Set $F = \{\omega \mid T(\omega) < \infty, (\omega, T(\omega)) \in B^c\}$. By Lemma 3.3, for each P_x , it holds that B is a predictable set of interval type, T is an $\{\mathcal{F}_t\}$ -stopping time, $F \in \mathcal{F}_{T-}$, $T_F := TI_F + (+\infty)I_{F^c}$ is a predictable time, and $1_B = 1_F 1_{\llbracket 0, T \rrbracket} + 1_{F^c} 1_{\llbracket 0, T \rrbracket} = 1_{\llbracket 0, T \rrbracket} + 1_{\llbracket T, \infty \rrbracket}$. Let ζ be the lifetime of $(X_t)_{t \geq 0}$, we define

$$\zeta_i = \zeta_{F^c} := \zeta I_{F^c} + (+\infty)I_F.$$

Note that for \mathcal{E} -q.e. $x \in E$, we have $\tau_{V_n} \uparrow \zeta = T$ P_x -a.s., therefore $I(\zeta) := \llbracket 0, \zeta \rrbracket \cup \llbracket \zeta_i \rrbracket = \llbracket 0, T \rrbracket \cup \llbracket T_{F^c} \rrbracket = B$ is a predictable set of interval type. Moreover, by the quasi-left continuity of Hunt process and the assumption that V_n has compact closure, we find that for any n and $x \in E$, $P_x\{S = \tau_{V_n} = \zeta < \infty\} = 0$ for any predictable time S . Hence $\zeta_i = T_{F^c}$ is the totally inaccessible part of ζ w.r.t. P_x for \mathcal{E} -q.e. $x \in E$. Finally, for arbitrary $\{U_n\} \in \Theta$, we have $\tau_{V_n \cap U_n} \uparrow \zeta = T$ P_x a.s. for \mathcal{E} -q.e. $x \in E$. Therefore $I(\zeta) = \cup_n \llbracket 0, \tau_{V_n \cap U_n} \rrbracket$ P_x -a.s. for \mathcal{E} -q.e. $x \in E$, which completes the proof. \square

4 Transformation formula for MAFs

In this section, we give a transformation formula for MAFs. We adopt the setting of Section 2. Suppose that $(\mathcal{E}, D(\mathcal{E}))$ is a quasi-regular semi-Dirichlet form on $L^2(E; m)$ satisfying Assumption 2.3. From the proof of Theorem 2.4, we can see that $M^{[u],c}$ is well defined whenever $u \in D(\mathcal{E})_{loc}$. Below is the main result of this section.

Theorem 4.1. *Suppose that $(\mathcal{E}, D(\mathcal{E}))$ is a quasi-regular semi-Dirichlet form on $L^2(E; m)$ satisfying Assumption 2.3. Let $m \in \mathbb{N}$, $\Phi \in C^1(\mathbb{R}^m)$, and $u = (u_1, u_2, \dots, u_m)$ with $u_i \in D(\mathcal{E})_{loc}$, $1 \leq i \leq m$. Then $\Phi(u) \in D(\mathcal{E})_{loc}$ and*

$$M^{[\Phi(u)],c} = \sum_{i=1}^m \Phi_{x_i}(u) \cdot M^{[u_i],c} \text{ on } I(\zeta), \quad P_x\text{-a.s. for } \mathcal{E}\text{-q.e. } x \in E.$$

The proof of the theorem will be accomplished at the end of this section by employing Theorem 4.3 below.

We fix a $\{V_n\} \in \Theta$ satisfying Assumption 2.3 and such that \tilde{h} is bounded on each V_n . Let X^{V_n} , $(\mathcal{E}^{V_n}, D(\mathcal{E})_{V_n})$, \bar{h}_n , etc. be the same as in Section 2. For $u \in D(\mathcal{E})_{V_n,b}$, we denote by $\mu_{<u>}^{(n)}$ the Revuz measure of $\langle M^{n,[u]} \rangle$. For $u, v \in D(\mathcal{E})_{V_n,b}$, we define

$$\mu_{<u,v>}^{(n)} := \frac{1}{2}(\mu_{<u+v>}^{(n)} - \mu_{<u>}^{(n)} - \mu_{<v>}^{(n)}). \quad (4.1)$$

Similar to [14, Lemma 3.1], we can prove the following lemma.

Lemma 4.2. *Let $u, v, f \in D(\mathcal{E})_{V_n, b}$. Then*

$$\int_{V_n} \tilde{f} d\mu_{<u, v>}^{(n)} = \mathcal{E}(u, vf) + \mathcal{E}(v, uf) - \mathcal{E}(uv, f).$$

For $u \in D(\mathcal{E})_{V_n, b}$, we denote by $M^{n, [u], c}$ and $M^{n, [u], d}$ the continuous and purely discontinuous parts of $M^{n, [u]}$, respectively; and denote by $\mu_{<u>}^{n, c}$ and $\mu_{<u>}^{n, d}$ the Revuz measures of $< M^{n, [u], c} >$ and $< M^{n, [u], d} >$, respectively. Then $M^{n, [u]} = M^{n, [u], c} + M^{n, [u], d}$ and

$$\mu_{<u>}^{(n)} = \mu_{<u>}^{n, c} + \mu_{<u>}^{n, d}. \quad (4.2)$$

Let $(N^{(n)}(x, dy), H^{(n)})$ be a Lévy system of X^{V_n} and $\nu^{(n)}$ the Revuz measure of $H^{(n)}$. Define $K^{(n)}(dx) := N^{(n)}(x, \Delta) \nu^{(n)}(dx)$. Similar to [6, (5.3.8) and (5.3.10)], we can show that

$$\begin{aligned} < M^{n, [u], d} >_t &= \left(\sum_{0 \leq s \leq t} (\Delta M_s^{n, [u], d})^2 \right)^p \\ &= \int_0^t \int_{V_n \cup \{\Delta\}} (\tilde{u}(x) - \tilde{u}(y))^2 N^{(n)}(X_s^{V_n}, \Delta) dH_s^{(n)} \end{aligned} \quad (4.3)$$

and

$$\mu_{<u>}^{n, d}(dx) = \int_{V_n \cup \{\Delta\}} (\tilde{u}(x) - \tilde{u}(y))^2 N^{(n)}(x, dy) \nu^{(n)}(dx). \quad (4.4)$$

For $u, v \in D(\mathcal{E})_{V_n, b}$, we define

$$\mu_{<u, v>}^{n, c} := \frac{1}{2}(\mu_{<u+v>}^{n, c} - \mu_{<u>}^{n, c} - \mu_{<v>}^{n, c}), \quad \mu_{<u, v>}^{n, d} := \frac{1}{2}(\mu_{<u+v>}^{n, d} - \mu_{<u>}^{n, d} - \mu_{<v>}^{n, d}). \quad (4.5)$$

Theorem 4.3. *Let $u, v, w \in D(\mathcal{E})_{V_n, b}$. Then*

$$d\mu_{<uv, w>}^{n, c} = \tilde{u} d\mu_{<v, w>}^{n, c} + \tilde{v} d\mu_{<u, w>}^{n, c}. \quad (4.6)$$

Proof. The argument for the proof of this theorem is similar to that of [14, Theorem 3.2]. We will only emphasize the differences caused by the jump part.

By quasi-homeomorphism (cf. [10, Theorem 3.8]) and the polarization identity, (4.6) holds for $u, v, w \in D(\mathcal{E})_{V_n, b}$ is equivalent to

$$\int_{V_n} \tilde{f} d\mu_{<u^2, w>}^{n, c} = 2 \int_{V_n} \tilde{f} \tilde{u} d\mu_{<u, w>}^{n, c}, \quad \forall f, u, w \in D(\mathcal{E})_{V_n, b}. \quad (4.7)$$

For $u, w \in D(\mathcal{E})_{V_n, b}$, we define

$$\eta_{u, w}^{(n)}(dx) = \int_{V_n \cup \{\Delta\}} (\tilde{u}(x) - \tilde{u}(y))^2 (\tilde{w}(x) - \tilde{w}(y)) N^{(n)}(x, dy) \nu^{(n)}(dx).$$

Then, by (4.1)-(4.5), we find that (4.7) is equivalent to

$$\int_{V_n} \tilde{f} d\mu_{<u^2, w>}^{(n)} = 2 \int_{V_n} \tilde{f} \tilde{u} d\mu_{<u, w>}^{(n)} + \int_{V_n} \tilde{f} d\eta_{u, w}^{(n)}, \quad \forall f, u, w \in D(\mathcal{E})_{V_n, b}. \quad (4.8)$$

For $k \in \mathbb{N}$, we define $v_k := kR_{k+1}^{V_n}u$. Then $v_k \rightarrow u$ in $D(\mathcal{E})_{V_n}$ as $k \rightarrow \infty$. By Assumption 2.3 and [16, Corollary I.4.15], we can show that $\sup_{k \geq 1} \mathcal{E}(v_k w, v_k w) < \infty$. Then, by [16, Lemma I.2.12], there exists a subsequence $\{(v_{k_l})\}_{l \in \mathbb{N}}$ of $\{v_k\}_{k \in \mathbb{N}}$ such that $u_k w \rightarrow u w$ in $D(\mathcal{E})_{V_n}$ as $k \rightarrow \infty$, where $u_k := \frac{1}{k} \sum_{l=1}^k v_{k_l}$. Note that $u_k \rightarrow u$ in $D(\mathcal{E})_{V_n}$ as $k \rightarrow \infty$ and $\|u_k\|_\infty \leq \|u\|_\infty$ for $k \in \mathbb{N}$. Moreover, $\|L^{V_n} u_k\|_\infty < \infty$ for $k \in \mathbb{N}$, where L^{V_n} is the generator of X^{V_n} . For $k, l \in \mathbb{N}$, we define $f_k := f \wedge (k\bar{h}_n)$ and $f_{k,l} := l\hat{G}_{l+1}^{V_n} f_k$.

Similar to [14, Theorem 3.2], to prove (4.8), we may assume without loss of generality that $f \geq 0$, $u = u_k$ and $f = f_{k,l}$.

For $0 < \delta < 1$, we have

$$\begin{aligned} & \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l}, m} [< M^{n, [u_k]} >_t^2] \\ &= \lim_{t \downarrow 0} \frac{2}{t} E_{f_{k,l}, m} \left[\int_0^t < M^{n, [u_k]} >_{(t-s)} \circ \theta_s d < M^{n, [u_k]} >_s \right] \\ &= \lim_{t \downarrow 0} \frac{2}{t} E_{f_{k,l}, m} \left[\int_0^t E_{X_s^{V_n}} [< M^{n, [u_k]} >_{(t-s)}] d < M^{n, [u_k]} >_s \right] \\ &\leq 2 < E [< M^{n, [u_k]} >_\delta] \cdot \mu_{<u_k>}^{(n)}, \widetilde{f_{k,l}} > . \end{aligned}$$

Note that by our choice of u_k , there exists a constant $D_k > 0$ such that $E_x(< M^{n, [u_k]} >_\delta) = E_x[(M_\delta^{n, [u_k]})^2] = E_x[(\tilde{u}_k(X_\delta^{V_n}) - \tilde{u}_k(X_0^{V_n}) - \int_0^\delta L^{V_n} u_k(X_s^{V_n}) ds)^2] \leq D_k$ for \mathcal{E} -q.e. $x \in V_n$. Letting $\delta \rightarrow 0$, we obtain by the dominated convergence theorem that

$$\lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l}, m} [< M^{n, [u_k]} >_t^2] = 0. \quad (4.9)$$

We have

$$\begin{aligned} \int_{V_n} \widetilde{f_{k,l}} d\mu_{<u_k^2, w>}^{(n)} &= \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l}, m} [< M^{n, [u_k^2]}, M^{n, [w]} >_t] \\ &= \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l}, m} [(\tilde{u}_k^2(X_t^{V_n}) - \tilde{u}_k^2(X_0^{V_n}))(\tilde{w}(X_t^{V_n}) - \tilde{w}(X_0^{V_n}))] \\ &= \lim_{t \downarrow 0} \frac{2}{t} E_{(f_{k,l} u_k) \cdot m} [(\tilde{u}_k(X_t^{V_n}) - \tilde{u}_k(X_0^{V_n}))(\tilde{w}(X_t^{V_n}) - \tilde{w}(X_0^{V_n}))] \\ &\quad + \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l}, m} [(\tilde{u}_k(X_t^{V_n}) - \tilde{u}_k(X_0^{V_n}))^2(\tilde{w}(X_t^{V_n}) - \tilde{w}(X_0^{V_n}))] \\ &:= \lim_{t \downarrow 0} [I(t) + II(t)]. \end{aligned}$$

Similar to [14, Theorem 3.2], we can show that

$$\lim_{t \downarrow 0} I(t) = 2 \int_{V_n} \widetilde{f_{k,l}} \tilde{u}_k d\mu_{<u_k, w>}^{(n)}.$$

Note that

$$\begin{aligned}
\lim_{t \downarrow 0} II(t) &= \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} [(M_t^{n,[u_k],c})^2 M_t^{n,[w]}] \\
&\quad + 2 \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} [(M_t^{n,[u_k],c})(M_t^{n,[u_k],d}) M_t^{n,[w],c}] \\
&\quad + 2 \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} [(M_t^{n,[u_k],c})(M_t^{n,[u_k],d}) M_t^{n,[w],d}] \\
&\quad + \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} [(M_t^{n,[u_k],d})^2 M_t^{n,[w],c}] \\
&\quad + \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} [(M_t^{n,[u_k],d})^2 M_t^{n,[w],d}] \\
&:= \lim_{t \downarrow 0} \{III_1(t) + 2III_2(t) + 2III_3(t) + III_4(t) + IV(t)\}.
\end{aligned}$$

Similar to [14, Theorem 3.2], we can show that

$$\lim_{t \downarrow 0} III_1(t) = 0. \quad (4.10)$$

By Itô's formula and the orthogonality of the continuous and purely discontinuous martingales, we get

$$\begin{aligned}
\lim_{t \downarrow 0} |III_2(t)| &\leq \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} [\langle M^{n,[u_k],c}, M^{n,[w],c} \rangle_t^2] \right\}^{\frac{1}{2}} \\
&\quad \cdot \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} [M_t^{n,[u_k],d}]^2 \right\}^{\frac{1}{2}}.
\end{aligned}$$

Similar to (4.10), we can show that $\lim_{t \downarrow 0} III_2(t) = 0$.

By Itô's formula and Burkholder-Davis-Gundy inequality, we get

$$\begin{aligned}
\lim_{t \downarrow 0} |III_4(t)| &= \lim_{t \downarrow 0} \left| \frac{1}{t} E_{f_{k,l} \cdot m} \left\{ \sum_{0 < s \leq t} M_s^{n,[w],c} (\Delta M_s^{n,[u_k],d})^2 \right\} \right| \\
&= \lim_{t \downarrow 0} \left| \frac{1}{t} E_{f_{k,l} \cdot m} \left\{ \int_0^t M_s^{n,[w],c} d \langle M^{n,[u_k],d} \rangle_s \right\} \right| \\
&\leq \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} \{ M_t^{n,[w],c*} \langle M^{n,[u_k],d} \rangle_t \} \\
&\leq \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} (M_t^{n,[w],c*})^2 \right\}^{\frac{1}{2}} \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} (\langle M^{n,[u_k],d} \rangle_t)^2 \right\}^{\frac{1}{2}} \\
&\leq C \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} (M_t^{n,[w],c})^2 \right\}^{\frac{1}{2}} \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} (\langle M^{n,[u_k],d} \rangle_t)^2 \right\}^{\frac{1}{2}} \\
&= C \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} \langle M^{n,[w],c} \rangle_t \right\}^{\frac{1}{2}} \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} (\langle M^{n,[u_k],d} \rangle_t)^2 \right\}^{\frac{1}{2}},
\end{aligned}$$

where $M_t^{n,[w],c*}$ denotes the maximum of $M_t^{n,[w],c}$, $\Delta M_s^{n,[u_k],d} = M_s^{n,[u_k],d} - M_{s-}^{n,[u_k],d}$ and C is a positive constant. Hence $\lim_{t \downarrow 0} III_4(t) = 0$. Similarly, we can show that $\lim_{t \downarrow 0} III_3(t) = 0$.

Finally, we estimate $IV(t)$. By Itô's formula and the dual predictable projection, we get

$$\begin{aligned}
IV(t) &= \frac{1}{t} E_{f_{k,l} \cdot m} (M_t^{n,[u_k],d})^2 M_t^{n,[w],d} \\
&= \frac{1}{t} E_{f_{k,l} \cdot m} \left\{ \sum_{0 < s \leq t} (M_s^{n,[u_k],d})^2 M_s^{n,[w],d} - (M_{s-}^{n,[u_k],d})^2 M_{s-}^{n,[w],d} \right. \\
&\quad \left. - 2M_{s-}^{n,[u_k],d} M_{s-}^{n,[w],d} (M_s^{n,[u_k],d} - M_{s-}^{n,[u_k],d}) - (M_{s-}^{n,[u_k],d})^2 (M_s^{n,[w],d} - M_{s-}^{n,[w],d}) \right\} \\
&= \frac{1}{t} E_{f_{k,l} \cdot m} \left\{ \sum_{0 < s \leq t} (\Delta M_s^{n,[u_k],d})^2 \Delta M_s^{n,[w],d} \right. \\
&\quad \left. + \sum_{0 < s \leq t} M_{s-}^{n,[w],d} (\Delta M_s^{n,[u_k],d})^2 + \sum_{0 < s \leq t} M_{s-}^{n,[u_k],d} \Delta M_s^{n,[u_k],d} \Delta M_s^{n,[w],d} \right\} \\
&= \frac{1}{t} E_{f_{k,l} \cdot m} \left\{ \int_0^t \int_{V_n \cup \{\Delta\}} (u_k(X_s^{V_n}) - u_k(y))^2 (w(X_s^{V_n}) - w(y)) N^{(n)}(X_s^{V_n}, dy) dH_s^{(n)} \right. \\
&\quad \left. + \sum_{0 < s \leq t} M_{s-}^{n,[w],d} (\Delta M_s^{n,[u_k],d})^2 + \sum_{0 < s \leq t} M_{s-}^{n,[u_k],d} \Delta M_s^{n,[u_k],d} \Delta M_s^{n,[w],d} \right\} \\
&:= IV_1(t) + IV_2(t) + IV_3(t).
\end{aligned}$$

We have

$$\lim_{t \downarrow 0} IV_1(t) = \int_{V_n} f_{k,l} d\eta_{u_k,w}^{(n)}$$

and, by Lemma 2.12 and (4.9),

$$\begin{aligned}
\lim_{t \downarrow 0} |IV_2(t)| &= \lim_{t \downarrow 0} \left| \frac{1}{t} E_{f_{k,l} \cdot m} \left\{ \int_0^t M_{s-}^{n,[w],d} d < M_{s-}^{n,[u_k],d} >_s \right\} \right| \\
&\leq \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} \{ (M_t^{n,[w],d})^* < M^{n,[u_k],d} >_t \} \\
&\leq \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} < M^{n,[w],d} >_t \right\}^{\frac{1}{2}} \left\{ \lim_{t \downarrow 0} \frac{1}{t} E_{f_{k,l} \cdot m} < M^{n,[u_k],d} >_t^2 \right\}^{\frac{1}{2}} \\
&= 0,
\end{aligned}$$

where $M_t^{n,[w],d*}$ denotes the maximum of $M_t^{n,[w],d}$. Similarly, we get $\lim_{t \downarrow 0} IV_3(t) = 0$. Therefore, the proof is complete. \square

Proof of Theorem 4.1 By virtue of Theorem 4.3, following the argument of the proof of [14, Theorem 3.10], we can prove Theorem 4.1. We omit the details here. \square

5 Examples

In this section, we consider some concrete examples. Note that our Theorems 2.4 and 4.1 are generalization of the corresponding results of [14], which were only given for local semi-Dirichlet forms without jump.

Example 5.1. (see [7] and cf. also [20]) Let (E, d) be a locally compact separable metric space, m a positive Radon Measure on E with full topological support, and $k(x, y)$ a nonnegative Borel measurable function on $\{(x, y) \in E \times E \mid x \neq y\}$. Set $k_s(x, y) = \frac{1}{2}(k(x, y) + k(y, x))$ and $k_a(x, y) = \frac{1}{2}(k(x, y) - k(y, x))$. Denote by $C_0^{lip}(E)$ the family of all uniformly Lipschitz continuous functions on E with compact support. Suppose that the following conditions hold:

$$(A.I) \quad x \rightarrow \int_{y \neq x} (1 \wedge d(x, y)^2) k_s(x, y) m(dy) \in L_{loc}^1(E; m).$$

$$(A.II) \quad \sup_{x \in E} \int_{\{y: k_s(x, y) \neq 0\}} \frac{k_a^2(x, y)}{k_s(x, y)} m(dy) < \infty.$$

Define for $u, v \in C_0^{lip}(E)$,

$$\eta(u, v) = \iint_{x \neq y} (u(x) - u(y))(v(x) - v(y)) k_s(x, y) m(dx) m(dy)$$

and

$$\mathcal{E}(u, v) = \frac{1}{2} \eta(u, v) + \iint_{x \neq y} (u(x) - u(y)) v(y) k_a(x, y) m(dx) m(dy).$$

Then, there exists $\alpha > 0$ such that $(\mathcal{E}_\alpha, C_0^{lip}(E))$ is closable on $L^2(E; m)$ and its closure $(\mathcal{E}_\alpha, D(\mathcal{E}_\alpha))$ is a regular semi-Dirichlet form on $L^2(E; m)$. Moreover, there exists $C > 1$ such that for any $u \in D(\mathcal{E}_\alpha)$,

$$\frac{1}{C} \eta_\alpha(u, u) \leq \mathcal{E}_\alpha(u, u) \leq C \eta_\alpha(u, u).$$

Therefore, our Theorems 2.4 and 4.1 hold for any $u \in D(\mathcal{E})_{loc}$ which satisfies Condition (S), in particular, for any $u \in D(\mathcal{E})$ by noting that $|k_a(x, y)| \leq k_s(x, y)$.

Example 5.2. (see [25]) Let G be an open set of \mathbb{R}^d . Suppose that the following conditions hold:

(B.I) There exist $0 < \lambda \leq \Lambda$ such that

$$\lambda |\xi|^2 \leq \sum_{i,j=1}^d a_{ij}(x) \xi_i \xi_j \leq \Lambda |\xi|^2 \quad \text{for } x \in G, \quad \xi \in \mathbb{R}^d.$$

(B.II) $b_i \in L^d(G; dx)$, $i = 1, \dots, d$.

(B.III) $c \in L_+^{d/2}(G; dx)$.

(B.IV) $x \rightarrow \int_{y \neq x} (1 \wedge |x - y|^2) k_s(x, y) dy \in L_{loc}^1(G; dx)$.

(B.V) $\sup_{x \in G} \int_{\{|x-y| \geq 1, y \in G\}} |k_a(x, y)| dy < \infty$, $\sup_{x \in G} \int_{\{|x-y| < 1, y \in G\}} |k_a(x, y)|^\gamma dy < \infty$ for some $0 < \gamma \leq 1$, and $|k_a(x, y)|^{2-\gamma} \leq C_1 k_s(x, y)$, $x, y \in G$ with $0 < |x-y| < 1$ for some constant $C_1 > 0$.

Define for $u, v \in C_0^1(G)$,

$$\begin{aligned} \eta(u, v) &= \frac{1}{2} \sum_{i=1}^d \int_G \frac{\partial u}{\partial x_i}(x) \frac{\partial v}{\partial x_i}(x) dx \\ &\quad + \frac{1}{2} \iint_{x \neq y} (u(x) - u(y))(v(x) - v(y)) k_s(x, y) dx dy \end{aligned}$$

and

$$\begin{aligned} \mathcal{E}(u, v) &= \frac{1}{2} \sum_{i=1}^d \int_G a_{ij}(x) \frac{\partial u}{\partial x_i}(x) \frac{\partial v}{\partial x_j}(x) dx + \sum_{i=1}^d \int_G b_i(x) u(x) \frac{\partial v}{\partial x_i}(x) dx \\ &\quad + \int_G u(x) v(x) c(x) dx \\ &\quad + \frac{1}{2} \iint_{x \neq y} (u(x) - u(y))(v(x) - v(y)) k_s(x, y) dx dy \\ &\quad + \iint_{x \neq y} (u(x) - u(y)) v(x) k_a(x, y) dx dy. \end{aligned}$$

Then, when λ is sufficiently large, there exists $\alpha > 0$ such that $(\mathcal{E}_\alpha, C_0^1(G))$ is closable on $L^2(G; dx)$ and its closure $(\mathcal{E}_\alpha, D(\mathcal{E}_\alpha))$ is a regular semi-Dirichlet form on $L^2(G; dx)$. Moreover, there exists $C' > 1$ such that for any $u \in D(\mathcal{E}_\alpha)$,

$$\frac{1}{C'} \eta_\alpha(u, u) \leq \mathcal{E}_\alpha(u, u) \leq C' \eta_\alpha(u, u).$$

Therefore, our Theorems 2.4 and 4.1 hold for any $u \in D(\mathcal{E})_{loc}$ which satisfies Condition (S), in particular, for any $u \in D(\mathcal{E})$ by noting that $|k_a(x, y)| \leq k_s(x, y)$.
